PRIVILEGED AND CONFIDENTIAL - PREPARED AT THE REQUEST OF COUNSEL

Maximum nodes per ring – facility ring processor

This is the maximum number of nodes the ring code will include in a "facility" ring connecting carrier switch locations. It is typical of common transmission engineering practices employed by existing carriers.

Regenerator spacing - facility ring processor

The ring processor uses this input to determine when optical regeneration is required on a span connecting two nodes on a SONET ring. It is a conservative value based on the technical specifications of commonly-available optical fiber and SONET optical transmitters and receivers. A very conservative estimate for maximum span loss accommodated by current long-reach optical interfaces operating at 1550 nm is 22 dB (including consideration for end-of-life deterioration and splicing). A conservative estimate for non-zero dispersion-shifted fiber attenuation is 0.24 dB/km. The maximum regenerator spacing, using these values, is 20 dB/ 0.24 db/km, or 91 km, which is about 57 miles.

CLLI rejection threshold, miles – facility ring processor

This is a modeling input assumption used to identify "outlier" locations in the construction of "core" rings; any location whose distance to the next closest location is greater than the threshold distance will be rejected from the ring calculations. The default value was selected by model developers as a reasonable threshold value for modeling purposes.

Long-reach optical modules can readily accommodate span losses of greater than 25 dB at 1550 nm. See, e.g.,

 $[\]frac{\text{http://www.cisco.com/en/US/products/hw/modules/ps2831/products}}{2\text{ See, }\textit{e.g., }\textit{Corning}^{\$}\textit{LEAF}^{\$}\textit{Optical Fiber Product Guide}}, P11107, March, 2003, Corning Incorporated.}$ The 0.24 dB/km value applies over the range 1525-1575 nm.
